ABSTRACT

We report a case of a 19-year-old young male presenting with thyrotoxicosis with inappropriately elevated TSH. Magnetic resonance imaging revealed a pituitary adenoma (8.2 x 9.7 mm), TRH stimulation test showed abnormal blunted TSH response, and serum glycoprotein hormone alpha-sub-unit was elevated. He had no family history of thyroid disease and TRβ genetic testing excluded resistance to thyroid hormone action. The diagnosis of thyrotropin-secreting pituitary adenoma (TSHoma) was presumed and long-acting somatostatin analogue was promptly initiated. After two months of octreotide treatment, serum TSH and FT3 returned to within normal ranges. Tumour resection by transsphenoidal surgery was performed and, ten days after surgery, clinical hypothyroidism was achieved, despite detectable TSH levels (TSH 1.02 µU/ml[RR 0.27-4.2]). Although the patient remained euthyroid for the following three years, there was a gradual biochemical elevation in the levels of TSH, FT4, and FT3 over time, reaching serum values above the normal limit in the third year after surgery. Imaging did not show neoplasm recurrence at this point. After two years, the patient presented with clinical manifestations of re-onset thyrotoxicosis, with MRI revealing a T2 hypersignal oval area compatible with a pituitary adenoma. Adenectomy was performed. Histopathological and immunohistochemical analyses revealed a pituitary adenoma with transcription factor PIT1 expression and positivity for TSH and PRL. TSHoma treatment may not be always effective in the first therapeutic approach and recurrences are a possibility, making follow-up essential. The present case highlights the heterogeneity of post-treatment cure criteria and their limitations.

KEYWORDS

Pituitary adenoma, thyrotoxicosis, hyperthyroidism, thyrotropin, neurosurgery

LEARNING POINTS

- Thyrotropin-secreting pituitary adenomas are rare benign tumours. Proper diagnosis can be challenging, requiring TSH autonomous production and differentiation from resistance to thyroid hormone action (RTH).
- Undetectable TSH levels one week after surgery and/or positive T3 suppression test or no response to TRH stimulation test seem to be the criteria with the best prognostic value post-treatment.
- Close clinical, biochemical and imaging follow-up is crucial to detect TSHoma recurrence.

CASE DESCRIPTION

A 19-year-old young male with depressive disorder, sustained mood changes and involuntary weight loss was referred to our center in 2016 due to thyrotoxicosis with inappropriately elevated TSH (TSH 6.83 µU/ml [Reference Range (RR) 0.27-4.2], FT3 7.79 pg/ml [RR 2.0-4.4], FT4 1.76 ng/dL [RR 0.93-1.7]).

Further investigation showed heterogeneous micronodular thyroid echostructure and high radioactive iodine homogeneous uptake on thyroid scintigraphy, with negative thyroid autoantibodies. Magnetic resonance imaging (MRI) revealed a pituitary tumour (8.2 x 9.7 mm). TRH stimulation test showed abnormal TSH blunted response and serum glycoprotein hormone alpha-sub-unit (α-GSU) (1.17 uUI/ml [RR 0.00-0.80]) and α-GSU/TSH molar ratio (α-GSU/TSH×1) were elevated, suggesting a thyrotropin-secreting pituitary adenoma. There was no family history of thyroid disease and TRβ genetic testing excluded resistance to thyroid hormone action (RTH).

TSHoma diagnosis was made and long-acting somatostatin analogue was promptly initiated. After two months of octreotide treatment, serum TSH and FT3 returned to within normal ranges (TSH 4.27 µU/ml [RR 0.27-4.2], FT3 4.54 pg/ml [RR 2.0-4.4], FT4 1.25 ng/dl [RR 0.93-1.7]). The patient underwent tumour resection by transsphenoidal surgery (TSS) and, ten days after surgery, clinical hypothyroidism was achieved, despite detectable TSH serum levels (TSH 1.02 µU/ml [RR 0.27-4.2], FT3 1.69 pg/ml [RR 2.0-4.4], FT4 0.50 ng/dl [RR 0.93-1.7]). At this point, the patient started levothyroxine supplementation. Histopathological analyses showed adeno- and neurohypophysis fragments with normal characteristics and no neoplasm identified.

Although the patient remained euthyroid for the following three years, there was a gradual biochemical elevation in the levels of TSH, FT4, and FT3 over time, reaching serum values above the normal limit in the third year after surgery (TSH 4.62 µU/ml [RR 0.27-4.2], FT3 4.42 pg/ml [RR 2.0-4.4]), instantly raising the suspicion of TSHoma recurrence. Imaging did not show neoplasm recurrence at this point.

Two years later, in 2021, during the COVID-19 pandemic, the patient exhibited significant mood changes and panic attacks with re-onset of thyrotoxicosis with inappropriately elevated TSH (TSH 5.03 µU/ml [RR 0.27-4.2], FT3 8.35 pg/ml [RR 2.0-4.4], FT4 1.89 ng/dl [RR 0.93-1.7]). MRI now revealed a T2 hypersignal oval area of approximately 8 mm, on the anterior and right lateral aspect of the adenohypophysis, allied with a slight increase in volume/height of the pituitary gland on that side and slight deviation of the pituitary stalk, compatible with an adenoma (Fig. 1).

Transsphenoidal adenectomy was performed for a second time and hypothyroidism with minimal serum TSH levels (TSH 0.09 µU/ml, FT3 1.41 pg/ml, FT4 0.34 ng/dl) was accomplished postsurgery. Histopathological and immunohistochemical analyses finally exposed a pituitary adenoma with transcription factor PIT1 expression and positivity for TSH and PRL. Genetic testing for AIP mutation was negative.

Figure 1. T2-weighted MRI - oval area of T2 hypersignal (closed arrow), with approximately 8 mm, on the anterior and right lateral aspect of the adenohypophysis, allied with a slight increase in volume/height of the pituitary gland on that side and a slight deviation of the pituitary stalk, compatible with an adenoma.

Surgical cure of this rare nosological entity was assumed and the patient is currently clinically euthyroid. The patient is maintaining annual clinical and analytical examination.

DISCUSSION

Thyrotropin-secreting pituitary adenomas are rare benign entities, accounting for 0.5-3% of all pituitary adenomas, demanding appropriate investigation[1,2]. RTH, an autosomal dominant disorder, is the main differential diagnosis, manifested with high FT4 and FT3 levels in the presence of non-supressed TSH, which contrasts with the biochemical pattern founded in primary hyperthyroidism[2]. Our case exemplifies the diagnostic course of "inappropriate TSH secretion syndrome" and how challenging its treatment can be.

HOSPITAL GRAND ROUNDS PROGRAMME

Support your local institution with the Hospital Grand Rounds programme. The Grand Rounds articles are Clinical-pathologic conference-style (CPC) contributions where the topic has a **strong educational value** and the case is discussed in-depth.

The institution will also be provided a space in the article where to introduce itself, its activities and main focus. Hospitals can be supported through the gift of **publication fee coupons**.

Articles of the Grand Rounds Programme from the same hospital can be aggregated in playlists (acceptance is subject to peer review).

HOSPITAL GRAND ROUNDS

UKC Maribor, *by Editorial Board Member Radovan Hojs*

University Medical Centre (UKC) Maribor, Slovenia, provides secondary and tertiary healthcare services to patients from Maribor and northeastern part of Slovenia. It has status of teaching hospital and it is learning base for medical students. The origin of UKC Maribor reaches back to the Maribor city hospital that has been treating patients since 14th century and constantly developing since its official establishment in 1799. Today UKC Maribor employs 3400 staff members, of them approx. 600 medical doctors.
Part of UKC Maribor is Clinic for Internal medicine that includes departments of Cardiology and Angiology, Gastroenterology, Endocrinology and Diabetology, Nephrology, Dialysis, Rheumatology, Haematology and Hematologic Oncology, Pulmonary Diseases, Nuclear Medicine, Internal Intensive Medicine and Emergency Medical Unit.

HOSPITAL GRAND ROUNDS

Public University Hospital Maggiore della Carità, Novara, Italy *by Editorial Board Member, Prof. Ettore Bartoli*

The Public University Hospital "Maggiore della Carità", Novara, Italy, is a 700-bed teaching hospital, with 2700 employees. Approximately 500 of these are medical doctors. It is the home Institution for the Medical School of the "Università del Piemonte Orientale". In its early days it was a branch of the University of Turin and it became autonomous in 1998. Today, it admits 150 medical students and 80 interns a year and is strongly committed to pursuing excellence in education and research. In fact, according to the most recent CENSIS survey, it ranks 6th out of the 37 state universities nationwide.
Despite its recent history as a university hospital, the roots of the "Maggiore" date back to the Middle Ages. Originally it was a charity institute dedicated to the Archangel Michael - hence the name "Casa di San Michele della Carità".It was founded in the XI century with the aim of helping the poor, the elderly and the pilgrims. The care activity was addressed to aiding the sick only later, starting from the end of the thirteenth century. In 1482, a Bull of Pope Sixtus IV imposed the union between the Hospital of "S. Michele" with the other seven hospitals in Novara, confirming the importance assumed by this institution in its urban context.
